

# Comment on LaCour (2014), “The Echo Chambers are Empty”

Gregory J. Martin\*

Emory University

May 29, 2015

## Abstract

This note describes a number of anomalies uncovered during an attempt to replicate the text-based measures of ideology in Michael LaCour’s “The Echo Chambers Are Empty: Direct Evidence of Balanced, Not Biased, Exposure To Mass Media.”

The recent publicity surrounding the retraction of Michael LaCour and Don Green’s *Science* paper on canvassing in gay marriage referenda campaigns reminded me of an experience I’d had (unsuccessfully) attempting to replicate some of LaCour’s other work last year. In light of the disturbing revelations regarding the *Science* paper, I decided to investigate more fully. This note describes the results of that exercise. Simply put, despite using the same dataset of news show transcripts and implementing the same method described in his paper, my results are not at all comparable to LaCour’s. LaCour’s text-based measures of news show ideology reported in “The Echo Chambers Are Empty” are very likely fabricated.

---

\*Thanks to Gaurav Sood for helpful comments.

## Background

A working paper of mine (Martin and Yurukoglu (2014)) estimates cable TV viewers' preferences for news with a like-minded slant. As part of that project, we estimate the ideological positioning of the three cable news channels by comparing their usage of certain phrases to the usage of those same phrases by members of Congress in the Congressional Record, a method pioneered by Matt Gentzkow and Jesse Shapiro in their work on newspaper slant.

My co-author, Ali Yurukoglu, came across LaCour's "Echo Chambers" paper, which contains (in Figure 1) a similar exercise. LaCour's figure shows precise estimates of ideological location for a number of individual cable news shows, with significant separation between various shows. For instance, LaCour's figure places *The O'Reilly Factor* at a location in the far right tail of the distribution of Congressional Republicans, and *Countdown with Keith Olbermann* in the far left tail of the distribution of Congressional Democrats. This was at odds with my experience; our results using this general approach had typically located all of the cable news outlets in centrist locations, with differences between the outlets that were directionally accurate but fairly small in magnitude. However, LaCour used both a different statistical approach and a different sample of transcript text than we had, and we thought his implementation might simply be better than ours at discriminating between outlets.

In late June of 2014, Ali emailed LaCour requesting the code that produced the figure. LaCour promptly responded with code written using the JAGS library. He did not share his transcript data. I attempted to run the code he provided on our sample of transcript text. LaCour's code ran, but after more than a day of running time returned all zeros for the channels' ideological positions. I decided it was possible that I had set it up incorrectly, as his code relied on a file with Congressional ADA scores that he didn't include, and I was guessing somewhat as to the format of the inputs. Given how long the code took to run and my inexperience with JAGS, I decided it wasn't worth figuring out what went wrong, and instead wrote my own version of his Bayesian model, following his description in the paper.<sup>1</sup> As input data I used our sample of cable news show transcripts, which come from LexisNexis.

---

<sup>1</sup>My code is implemented in Stan and is available at [https://www.dropbox.com/s/ouvu7vyzeun96ki/replication\\_code\\_data.zip?dl=0](https://www.dropbox.com/s/ouvu7vyzeun96ki/replication_code_data.zip?dl=0).

The Savage Nation	The Radio Factor
The Mark Levin Show	Fox News Online
The Rush Limbaugh Show	The Stephanie Miller Show
The Laura Ingraham Show	The John and Ken Show
The Sean Hannity Show	The Bill Press Show
The Beltway Boys	The Thom Hartmann Show
The Alan Colmes Show	Geraldo at Large

Table 1: Shows with ideology estimates in LaCour’s Figure 1 that do not exist in the LACC database.

The results of this exercise looked quite similar to the results I had gotten previously using a different statistical method,<sup>2</sup> and unlike LaCour’s plot. At this point I chalked up the differences to the difference in the underlying text sample, and, deciding that the Bayesian approach was not superior, returned to the method I had been using.

I have now applied the method to the UCLA Closed Caption (LACC) archive of news show transcripts, the same dataset that LaCour reports using in his paper.<sup>3</sup> The results of this direct replication look much more similar to my previous results than they do to the results reported by LaCour. The discrepancies are not accounted for by differences in the samples of text, and they are also not due to differences in statistical methodology.

## Results

Figure 2 shows my replication of LaCour’s analysis, the original version of which is displayed in Figure 1. There are at least three major irregularities in LaCour’s reported results.

**Missing channels** First and most obviously, LaCour’s figure includes estimates of ideological positioning for a number of radio shows, such as *The Radio Factor* and *The Savage Nation*, that do not appear at all in the UCLA closed caption archive on which LaCour’s estimates are supposedly based. LaCour does not cite any additional sources for text from these shows. Table 1 lists these shows.

<sup>2</sup>We used an Elastic Net approach, as opposed to LaCour’s Bayesian implementation.

<sup>3</sup>I’ve also run LaCour’s code on this dataset, and reproduced the all-zero outputs I had found previously.

Figure 1: Mapping Television and Radio News Programs to Congressional Ideology

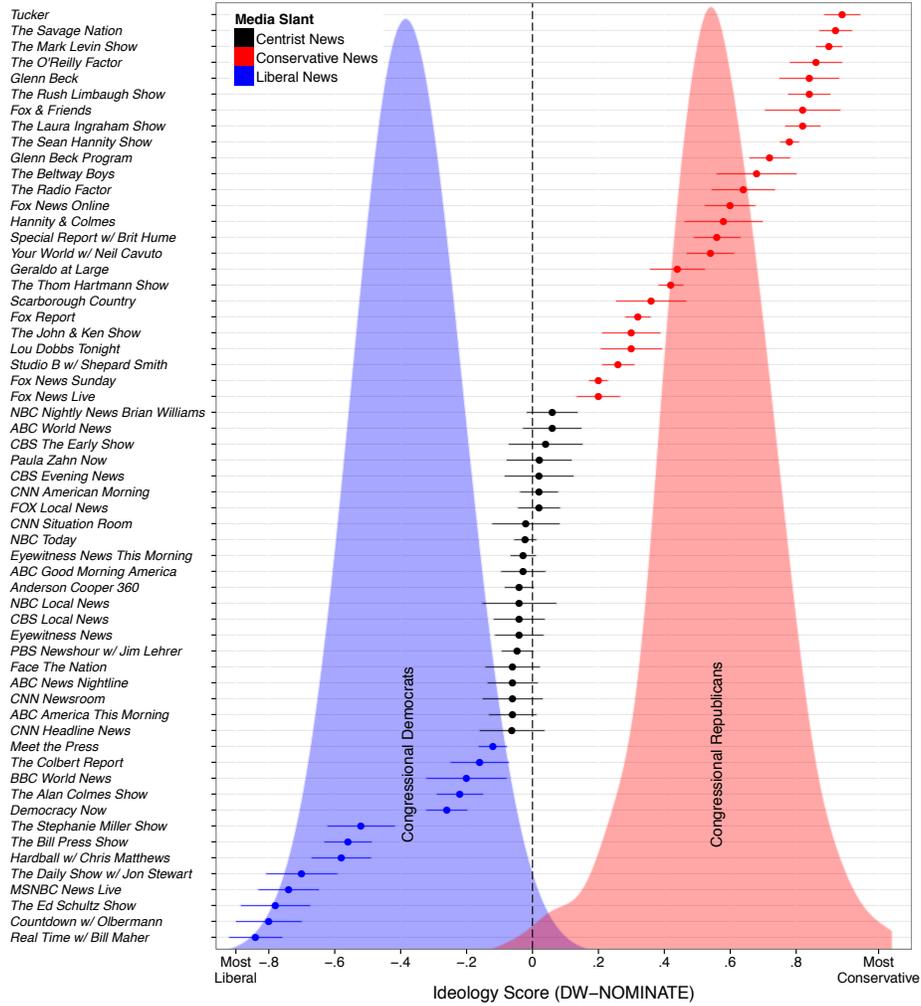

Figure 1: LaCour Figure 1: Original

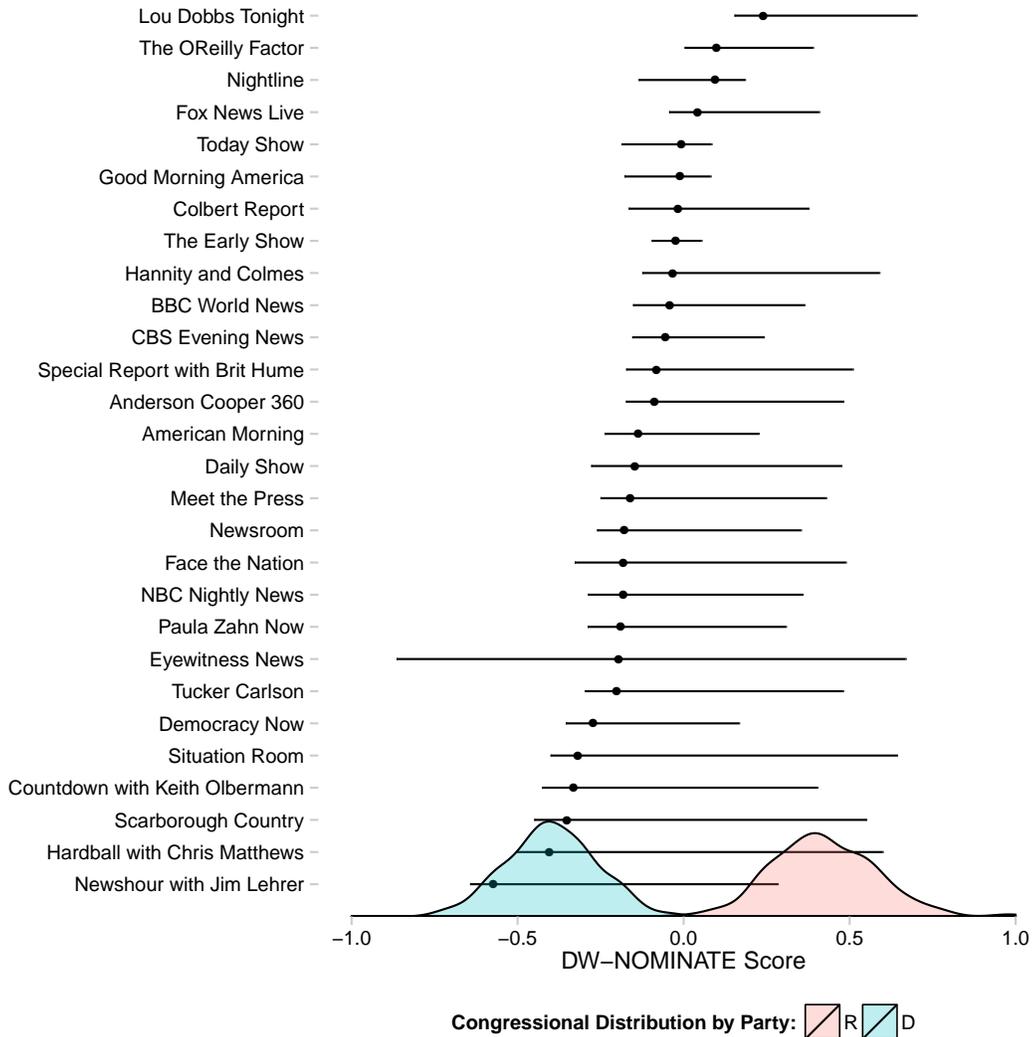

Figure 2: LaCour Figure 1: Replication. Dots are the median of 10,000 parameter samples generated by RStan’s implementation of the Metropolis-Hastings algorithm. Bars represent the central 95% interval of these samples. I generated samples using ten independent MCMC chains with 2,000 samples, each of which discarded a burn-in phase of the first 1,000 draws. The density estimates are the distributions of DW-NOMINATE first dimension scores for Congressional Democrats and Congressional Republicans.

In addition, there are shows that do appear in the LACC database, but not until after 2006. For example, *Real Time with Bill Maher* appears first in 2008. LaCour’s description of Figure 1 says that it plots “language-based estimates of the ideological slant of news programs in 2006.” This statement cannot be correct for those shows, like Bill Maher’s, that do not appear in LACC until after 2006. In all, I was able to locate 28 of the 60 shows claimed by LaCour’s Figure 1 in LACC in 2006. I used text from episodes of these shows that aired in 2006 to compute counts of the 1000 most-partisan phrases published by Gentzkow and Shapiro (2010).<sup>4</sup>

**Ideological Separation of Shows** LaCour’s Figure 1 identifies a number of prominent Fox News shows, such as *The O’Reilly Factor* and *Hannity & Colmes*, as being more conservative than the median Republican in Congress. He also places MSNBC shows such as *Countdown with Keith Olbermann* and Comedy Central shows like *The Daily Show* well to the left of the median Democrat in Congress.

In contrast, estimates from my replication are clustered close to the center of the DW-NOMINATE scale. Only two shows, PBS’ *Newshour with Jim Lehrer* and MSNBC’s *Hardball with Chris Matthews*, are estimated to the left of the median Congressional Democrat. No shows are estimated to be to the right of the median Congressional Republican. While the left-right ordering generally conforms to expectations, there are a number of unexpected results in the replication figure that do not appear in LaCour’s original. For example, ABC News’ *Nightline* is estimated to be one of the most conservative programs, as is NBC’s *The Today Show*.

**Confidence Intervals** The most dramatic difference between LaCour’s original figure and the replication is the degree of precision each claims. LaCour’s figure plots extremely narrow Bayesian credible intervals, the majority of which do not overlap zero. In contrast, the credible intervals in the replication are very wide, reflecting the imprecision inherent in text-based measures of ideology, and the simple fact that partisan-indicative phrases in the Congressional Record are not terribly common on television news. Many of the intervals cover most of the DW-NOMINATE scale, reflecting little additional information gained from the phrase counts compared to the

---

<sup>4</sup><http://www.icpsr.umich.edu/icpsrweb/ICPSR/studies/26242>

priors.<sup>5</sup> For example, although Jim Lehrer’s *NewsHour* has the most extreme left-wing estimated ideology of the shows in the database, *NewsHour*’s confidence interval does not reject the show having the ideology of a moderate Republican such as Virginia senator John Warner.

In the replication, only one show, *Lou Dobbs Tonight*, has a credible interval that does not overlap zero. Applying LaCour’s criterion, *Lou Dobbs Tonight* would be classified as “conservative news,” while all the remaining shows would be classified as “centrist news.” Achieving LaCour’s claimed degree of precision would require a corpus of text many times the size of the LACC database.

### Other Discrepancies

- Appendix A contains a lengthy verbatim excerpt from Gentzkow and Shapiro (2010) that is not identified as such. Compare Figures 3 and 4.
- LaCour’s code references a data file apparently provided by Tim Groseclose, `/Users/michaellacour/Dropbox/Papers/MediaBias/Groseclose/counts.csv`. This is the only data input to the code.<sup>6</sup> Groseclose has collected data on media citations to think tanks, not the usage of phrases as in the method described in the paper. Furthermore, it is apparent from the code that the number of media outlets in this file is 20 (the number in Tim Groseclose’s dataset), not the 60 that LaCour reports in the figure; LaCour’s estimation code sets the variable `N.news=20`.
- LaCour’s description of the model in Appendix A says that news show ideology priors are distributed “normally with a mean of 50.06 and precision .001. 50.06 is an estimate of the average United States voter’s ADA score, where 0 is the most liberal and 100 is the most conservative.” However, Figure 1 reports ideologies in terms of DW-NOMINATE score, which range from -1 to 1. Additionally, his equation above this text description indicates that the priors are uniform on 0 to 100, rather than normal; the code matches the text description and not the equation. I used DW-NOMINATE scores to match his figure, and chose a prior that is uniform on the range of the DW-NOMINATE scale.

---

<sup>5</sup>Priors are distributed uniform on  $[-1,1]$ , the range of the DW-NOMINATE scale.

<sup>6</sup>LaCour did not provide this file.

Let  $f_{pld}$  and  $f_{plr}$  denote the total number of times phrase  $p$  of length  $l$  (two or three words) is used by Democrats and Republicans, respectively. Let  $f_{\sim pld}$  and  $f_{\sim plr}$  denote the total occurrences of length- $l$  phrases that are *not* phrase  $p$  spoken by Democrats and Republicans, respectively. Let  $\chi_{pl}^2$  denote Pearson's  $\chi^2$  statistic for each phrase:

$$(1) \quad \chi_{pl}^2 = \frac{(f_{plr}f_{\sim pld} - f_{pld}f_{\sim plr})^2}{(f_{plr} + f_{pld})(f_{plr} + f_{\sim plr})(f_{pld} + f_{\sim pld})(f_{\sim plr} + f_{\sim pld})}$$

The second step identifies phrases that are diagnostic of the speaker's political party. If the counts  $f_{pld}$  and  $f_{plr}$  are drawn from (possibly different) multinomial distributions,  $\chi_{pl}^2$  is a test statistic for the null hypothesis that the propensity to use phrase  $p$  of length  $l$  is equal for Democrats and Republicans. This statistic conveniently summarizes the political asymmetry in the use of the phrase. (More naive statistics, such as the ratio of uses by Republicans to uses by Democrats, would tend to select phrases that are used only once by

Republicans and never by Democrats, even though pure sampling error could easily generate such a pattern.)  $\chi_{pl}^2$  is also simple to compute, in the sense that it requires only two calculations per phrase: the number of uses by Republicans and the number of uses by Democrats.

Figure 3: Excerpt from Gentzkow and Shapiro (2010), pp. 43-44

To select the phrases for analysis, I let  $f_{pld}$  and  $f_{ptr}$  denote the total number of times phrase  $p$  of length  $l$  (two words) is used by Democrats and Republicans, respectively. Let  $f \sim pld$  and  $f \sim ptr$  denote the total occurrences of length- $l$  phrases that are not phrase  $p$  spoken by Democrats and Republicans, respectively. Let  $x_{pl}^2$  denote Pearson's  $x^2$  statistic for each phrase:

$$x_{pl}^2 = \frac{(f_{ptr}f \sim pld - f_{pld}f \sim ptr)^2}{(f_{ptr} + f \sim pld)(f_{pld} + f \sim ptr)(f_{pld} + f \sim ptr)(f_{ptr} + f \sim ptr)}$$

I select the phrases for the analysis as follows:

1. I select the 1000 phrases of each length  $l$  with the greatest values of  $x_{pl}^2$  for a total of 1000 phrases.
2. I compute the total number of times that each phrase appeared in television and radio programs closed captioning text in the UCLA Television News Archive for 2006.

The second step identifies phrases that are diagnostic of the speaker's political party. If the counts  $f_{pld}$  and  $f_{ptr}$  are drawn from (possibly different) multinomial distributions,  $x_{pl}^2$  is a test statistic for the null hypothesis that the propensity to use phrase  $p$  of length  $l$  is equal for Democrats and Republicans. This statistic conveniently summarizes the political asymmetry in the use of the phrase. (More naive statistics, such as the ratio of uses by Republicans to uses by Democrats, would tend to select phrases that are used only once by Republicans and never by Democrats, even though pure sampling error could easily generate such a pattern.)  $x_{pl}^2$  is also simple to compute, in the sense that it requires only two calculations per phrase: the number of uses by Republicans and the number of uses by Democrats.

Figure 4: Corresponding excerpt from LaCour (2014), pp. 33

- LaCour claims in Appendix A that he chose a very diffuse and uninformative prior for the speaker and phrase fixed effects,  $\alpha_i$  and  $\beta_i$ .<sup>7</sup> As these parameters have direct empirical counterparts, choosing such a “flat” prior is unnecessary, and will tend to slow convergence of the MCMC chains. This choice makes it even less likely that LaCour achieved his claimed precision using the code provided, which uses a single MCMC chain of 10,000 draws, of which only the first 100 were discarded as a “burn-in.”

I kept LaCour’s normally-distributed assumption on these parameters, but initialized the mean and variance of each using its natural empirical counterpart (the average usage of each phrase across all shows, and the total use of the set of 1000 phrases by each show).

- There are a number of phrases in the Gentzkow-Shapiro set that appear very infrequently on TV. Including these phrases in the estimation routine will tend to further decrease precision and slow convergence. I excluded any phrase that did not appear at least 20 times (in total, across all shows) in the TV transcript data. I further excluded Congresspeople who did not use the phrases in the G-S set of 1000 at least 100 times (in total, across all the phrases) in the 109th Congress.<sup>8</sup> These steps left me with a set of 302 Congresspeople and 509 phrases.

---

<sup>7</sup>His code matches this description.

<sup>8</sup>LaCour does not mention taking these steps, but both have the effect of increasing precision, which makes his claimed credible intervals even less likely.
